

## BigML Evaluation Cheat Sheet

### Evaluation Configuration

#### Sampling

Sampling					
	Ordering				
Option	Description	Default	API Name	Option	Description
Rate	Sets the proportion of the dataset you want to consider between 0% and 100%.	100%	sample_rate	Deterministic shuffling	Ensures the row shuffling of a dataset is always the same, so that evaluating a model from the same dataset always yields the same results.
Range	Specifies a subset of instances from which to sample, e.g., from instance 5 to instance 1000. The <b>rate</b> you set will be computed over the <b>Range</b> configured.	(1, max_rows_in_dataset)	range	Linear	Selects the instances in the order they are listed to build the evaluation. If you know that your instances are already in random order, see the shuffling to linear so that the evaluation will be constructed faster.
Sampling	Allows you to choose between a random sampling or a deterministic sampling. When using deterministic sampling the random-number generator will always use the same seed, producing repeatable results.	Random	seed	Random shuffling	Takes a different sampling each time you evaluate your model.
Replacement	Allows a single instance to be selected multiple times. Sampling without replacement ensures that each instance cannot be selected more than once.	False	replacement	<b>Operating kinds for Ensembles</b>	
Out of bag	Selects only the out-of-bag instances for the currently defined sample. If an instance is not selected as part of a sample, it is considered out of bag. It is only selectable when a sample is deterministic and the sample rate is less than 100%.	False	out_of_bag	Probability	Averages the per-class probability distributions for all trees in the ensemble and predicts the class with higher probability. For regression ensembles, the global prediction is the mean of the individual predictions.
				Confidence	Averages the per-class confidences distributions for all trees in the ensemble and predicts the class with higher confidence. For regression ensembles, the global prediction is the mean of the individual predictions weighted by the expected error.
				Votes	Gives one vote to each model in the ensemble. For classification models, the category with the majority of votes wins. For regression models, the global prediction is the mean of the individual predictions.

#### Missing Strategies

Missing Strategies					
	Default		API Name		
Option	Description	Default	API Name	Default	API Name
Last prediction	Returns the parent node prediction when a missing value is found in the testing data for a decision node.	True	missing_strategy	False	operating_kind:confidence
Proportional	Recombines the subtrees predictions based on the proportion of data in each subtree when a missing value is found in the input data for a decision node.	False	missing_strategy	False	operating_kind:votes
